

How do you manage a user's session?

- By performing the following to servlets that need to remember a user's state:
 1. When the user requests a servlet, in addition to sending the response, the servlet also sends a token or an identifier.
 2. If the user does not come back with the next request for the same or a different servlet, that is fine, the token/identifier is sent back to the server
 3. Upon encountering the token, the next servlet should recognize the identifier and can do a certain action based on the token.
 4. When the servlet responds to the request, it also sends the same or a different token.
 5. This goes on and on with all the servlets that need to remember a user's session.
